

-1 is always last item

Day-5

Lists

List is a container, used to store multiple values inside one variable.

`Fruits = ["apple", "banana", "mango"]`

indexing is getting one specific item from list using position number

`Fruits[0]`

counting from back is negative indexing

Slicing is taking a portion/section/part of list

`List_name[start : stop]`

`Fruits = ["apple", "banana", "mango", "orange", "grapes"]`

`print(Fruits[1:4])`

start at 1 → stop before 4

Slicing returns multiple items together it is a list

`[ : 3 ]` → From beginning to some point

`[ 2 : ]` → " some point to end

`[ -3 : ]` → last few items

`[ : -1 ]` → everything except the last item

`append` used to add one new item to the end of list
`Fruits.append("berries")`

If we try to add multiple items with `append` it creates list inside

`a = ["a", "b", "c"]`

`a.append(["d", "e"])`

`a = ["a", "b", "c", ["d", "e"]]`

extend()

adds multiple items to end of the list individually

```
fruits.extend(["d", "e"])  
fruits  
['a', 'b', 'c', 'd', 'e']
```

remove()

remove items from list giving its value

```
fruits.remove("banana")
```

remove uses value not index

in numbers first occurrence is removed

```
a = [1, 2, 3, 4, 2, 5, 2]
```

```
a.remove(2)
```

```
a  
[1, 3, 4, 2, 5, 2]
```

pop() → nothing inside pops last item

removes items from list by index

```
fruits.pop(1)
```

to store the popped value

```
a = fruits.pop(1)
```

sort()

used to arrange items of a list in order.

```
n = [40, 10, 30, 20]
```

```
n.sort()
```

```
n  
[10, 20, 30, 40]
```

For alphabet it sorts from a → z

reverse()

reverses the items in list

```
fruits = ["apple", "banana", "mango", "orange"]  
fruits.reverse()
```

```
fruits  
['orange', 'mango', 'banana', 'apple']
```

ascending
default
