

Day 1

`mkdir` → Creates a new folder whenever you currently are in the terminal `mkdir day-1`

`cd` → moves you into another folder `cd day-1`

`pwd` → prints where you are

`python3 -m venv venv`

`python3` → calls python itself

`-m` → "run" a module python comes with bunch of built-in modules

`venv` (first one) → name of the built-in module we're using! it's a built-in virtual environment tool.

"Use Python 3 to run built-in venv tool"

`venv` (second one) → name of the folder it'll create. create a environment and put it in a folder called venv.

python creates folder called venv/ inside day-1

puts → own copy of Python

→ own pip

→ empty site-packages/

→ an active script

separate globally to isolated
activate each new session

`source venv/bin/activate`

`source` → read this file & execute everything inside it

`venv/bin/` → going in venv folder then into bin

`activate` → This actually activates python & pip inside venv/

`deactivate`

to remove venv

`pip install pandas request`

library
library
library

`pip freeze > requirements.txt`

`pip freeze` → looks at everything currently installed in your active venv and print it out as a list with exact version numbers.

`>` → redirect operator → shell feature → take everything in screen printed and rewrite it into a file

`requirements.txt` → universal - saves everything inside here

`touch .gitignore`

`code .gitignore`

`venv/`
`__pycache__/`
`*.pyc`
`.env`

→ never track these folders, ever

→ code this →

→

→

* → Interview

Q1 A virtual environment solves dependency conflicts. If project A needs pandas version 1.3 & B needs 2.1, we can't have both installed globally at the same time. One overwrites other break the project. It gives each project its own isolated Python & its own packages so they never interfere with each other.

Q2 I should have included `requirements.txt`, generated with `pip freeze > requirements.txt`. My teammate creates a new virtual environment activates it, then runs `pip install -r requirements.txt` - the `-r` flag tells pip to read the file & install every package at the exact pinned version.
